Inst : Institute of Biology, Bulgarian AS.  
Title : The Chronic Form of Radiation Sickness in Rabbits.

Orig Pub: Izv. In-ta biol. B"lg. AN, 1956, 7, 231-278.

Abstract: The daily irradiation of rabbits (until death) with doses of 11, 22, 33, and 45 r, the lethal doses and the time of survival were correspondingly 3333, 3520, 3960, 3000 r and 345, 185, 140 and 80 days. The erythrocyte count in the peripheral blood decreased slowly within the first week after the

Card 1/3

BULGARIA / Human and Animal Physiology. Action of      T  
Physical Agents.

Abs Jour: Ref Zhur-Biol., No 9, 1958, 41830.

Abstract: start of the irradiation. The Hb content of the blood increased until the 62nd day of irradiation, following which it decreased. The leucocytes of the peripheral blood underwent phasic changes: the initial brief leucopenia was replaced by an initial leucocytosis, passing into leucopenia with decrease of the number of lymphocytes, as well as granulocytes, with morphological changes of the blood cells, followed by a period of increase and fluctuation of the leucocyte count (primarily granulocytes); then again a phase of resistant leucopenia, brought about by decrease of hypersegmented leucocytes, the appearance of myelocytes and manifestations of degenerative changes in the white blood cells and erythrophagocytosis. The thrombocyte

BULGARIA / Human and Animal Physiology. Action of      T  
Physical Agents.

Abs Jour: Ref Zhur-Biol., No 9, 1958, 41830.

Abstract: count in the peripheral blood steadily decreased. Damage of the bone marrow appeared early; aplasia of the bone marrow was observed only in rabbits irradiated with 45 r doses, and it appeared only briefly before death. The cyclical character of the peripheral blood reactions in chronic irradiations is associated by the authors with the action of the ionizing irradiations on the CNS, and the occurrence in the CNS of processes of stimulation and inhibition affecting each other. -- V. A. Shaternikov.

1254. REMOTE (AS TO LOCATION) EFFECT AS HYPERERGIC REACTION IN  
RADIATION THERAPY OF MELANOMA (Bulgarian text) - Dimitrov  
M. K. and Boeva M. N. Distr. Onkol. Disp., Sofia - SAVR. MED. 1958,  
9/5 (102-104)

A case of melanoma with disseminated metastases treated with X-ray therapy  
is reported. Complications under the form of acute articular rheumatism and  
rheumocarditis developed as a result of the treatment itself. The authors connect  
these complications with the quick disintegration of the tumour masses under the  
influence of the irradiation. (XIV, 5, 6, 16)

358. Dimitry N. The influence line of the second-order theory and some practical formulas (in German), *Bauingenieur* 28, 1, 10-22, Jan. 1953.

Approximate formulas are given for moments and deflections in beams under combined transverse and end loads. They are obtained as a first approximation solution of the integrodifferential equation for the bending moment. Author states that the basic results were derived previously from more elementary considerations by Moersch and Dürchinger, but he seems unaware of similar American work (e.g., Reark, "Formulas for stress and strain," McGraw-Hill Book Co., Inc., New York, 1943, p. 135). Paper also shows how the formulas for the deflections may be used to find approximate values for the buckling loads in statically indeterminate configurations. The style of the report is clumsy, and reviewer feels that unnecessarily heavy mathematical arguments are used for an essentially elementary problem.

TITLE: Kinetics of super-rapid development. 1. A method for the study of super-rapid development

SOURCE: Zhurnal nauchnoy i prikladnoy fotografii i kinematografii, no. 3, 1963, 161-164

TOPIC TAGS: development, kinetics, density of color, density of picture color, super-rapid density recorder

ABSTRACT: A method was devised permitting the measurement of the color density in photographic films during the process of super-rapid developing. It consisted in taking a series of pictures at the rate of 32 to 1500 shots per second of the experimental film, while the film was being immersed in a developer in a transparent cuvette. Standards of color density were prepared by developing and fixing squares of film by the usual method, where the time of exposure to the developer was recorded. These standards were either pasted on the cuvette or placed inside, so that the camera took simultaneous pictures of the densities of the experimental

film as well as of the standards, the densities being due solely to the amount of metallic silver. The recording began while the experimental film was not yet immersed in the developer, and the moment it touched the surface, as well as during immersion, was meticulously recorded. The negatives were taken with a movie camera with both long and short focal lens. Since the contrast in an optical reproduction on a film is always less than the one in the photographed object, it was found that while the densities in the object changed from 0 to 2.7 units, those of their negative pictures varied only between 1.2 and 0.65 units. It is claimed that this method permits the recording of continuously changing densities of photographic materials in the process of development, with a precision of 0.03-0.05 units. Orig. art. has: 3 charts.

TITLE: The study of hyperspeed development kinetics. 2. Determining duration of various stages in film development

SOURCE: Zhurnal nauchnoy i prikladnoy fotografii i kinematografii, v. 9, no. 4, 1964, 254-259

TOPIC TAGS: photographic film, camera, silver deposit, emulsion, 17 T film, double negative type A film, Kiev 16S 2 camera, SKS 1M camera

ABSTRACT: The method of I. B. Blyumberg and R. V. Dimitrov (Zh. nauchn. i prikl. fotogr. i kinematogr., 1963, 8, 161) were used to determine the photographic density continuously during film development. Two types of movie cameras were used: the Kiev 16S-2 camera, 64 frames/sec and the SKS-1M camera with 500 frames/sec in white light. The development processes investigated were: swelling of film layer, penetration into this layer of the alkali, temperature front, induction period, and visible reduction of silver. The films used in the investigation were isopanchromatic films 17-T and Double-negative type A motion picture films. The  $D(t)$  curves of the following cases were constructed: dry films

ACCESSION NR: AP4043037

and water-swollen films at 20C temperature immersed in the developer and heated to 60C; dry films and water-swollen films heated to 60C and immersed in developer at same temperature; films (swollen in alkali and sulfide solutions at 60C) immersed in developer at the same temperature; films swollen in developer at 60C and immersed in alkali and sulfide solutions at the same temperature; and exposed films, with preliminary swelling in the developer at 60C. The developer for the double-negative films was the same as for those of type 17-T except for the exclusion of the benzotriazole component. The maximum value of D in the D versus t curves for type 17-T film was 2.5, attained at various time rates from 2.2 to 1.0 seconds, depending on the process under study. The double-negative films showed no such maxima in D. The results also show the diffusion rates of the various developers used to be almost identical. The highest rate of the development process was registered by the AgHal reduction reaction. "The authors express their deep gratitude to I. B. Blyumberg, Yu. Ye. Usanov and V. A. Karpov for assisting in the work." Orig. art. has: 5 figures and 1 table.

Abstract: To replenish lacks in course fodder in Southern  
Bulgaria, corn panicles are cut at the height of  
the attachment of the cob during the phase of milky  
ripeness. Tests conducted under production condi-  
tions showed that this method lowers the grain  
yield not less than by 8%.
